- Layered sequence of solidified lava flows.
  - Porous, permeable flow tops can provide storage capacity.
- 
- Potential for rapid mineral trapping due to Ca, Mg and Fe(II)-rich mineralogy.
  - Pilot-scale injections show compelling evidence of mineral trapping on short time scales.

## Relevance for BP: CCS and the energy transition

---

- Basalt can provide **alternative CO<sub>2</sub> storage capacity** when sedimentary formations are **absent or costly to develop**.
  - Possible examples include: India, Iceland and the NW-U.S.A.
- 
- Stability and security of mineral trapping may **improve prospects for building and maintaining social license** for CCS deployment.
- 
- Mineral trapping on short time scales may **significantly reduce the risks and costs** associated with **postinjection monitoring and verification**.

# Open questions before large-scale implementation

---

- How will chemical reactions alter the formation?
    - Porosity
    - Permeability
    - Formation integrity
  - Can we control where and when chemical reactions take place?
- 
- Can a full-scale project expect mineralization on political time scales?
  - To what extent do the ‘chemical details’ matter?
    - Exact mineralogy
    - Formation water composition
- 
- **We need a flexible, efficient modeling tool.**

## 4. Conclusions

# Development of an efficient numerical simulation method

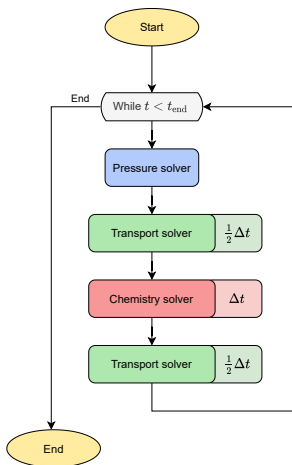

Modeling of CO<sub>2</sub> injection in reactive rocks is a complex problem:

- Flow of two phases, with CO<sub>2</sub> dissolving into formation water.
- An arbitrarily large number of chemical reactions.
- A rock formation that changes over time.

# Development of an efficient numerical simulation method

- An efficient fluid flow model of CO<sub>2</sub> injection in saline aquifers.
- A highly customizable geochemistry solver.
- Combined in an operator splitting algorithm.

**Figure 9:** We are interested in the percentage of CO<sub>2</sub> that has mineralized over time.

## Putting the model's efficiency to use

- Investigate how mineralization time depends on reservoir properties:
    - Dip angle
    - Permeability
    - Initial porosity
- 
- Identify a range of possible values for real systems.
  - Analyze simulation results for many different combinations of values.

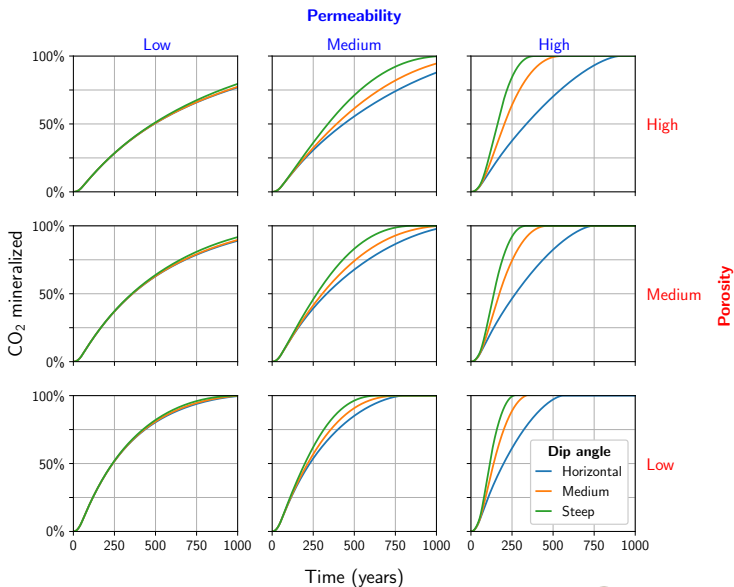

**Figure 10:** Do reservoir properties have a large impact on mineralization time?

# What if chemical reactions were much faster?

## Estimated loss of permeability

---

- Mineral reactions can alter the **porosity** of the formation, which will in turn affect **permeability**.
  - This may result in an unacceptable **decrease in injectivity**.
- 
- There is not yet a generally accepted **porosity-permeability relationship** for basalt.
  - To get a **first estimate**, assume that basalt behaves like sedimentary formations and use a commonly used **relationship for sandstones**.

## Conclusions

---

- Basalt formations may provide **alternative storage capacity** to supplement that of conventional reservoirs.
- 
- Consistent with previous research, CO<sub>2</sub> injection in basalt was observed to result in **significant mineral trapping** due to the reactivity of the rock.
- 
- However, our results indicate that an **increased scale of injection** may result in mineralization times that are **orders of magnitude longer** than those observed in small-scale pilot injections.
